HEAT TRANSFER VIVA QUESTIONS AND ANSWERS

Heat transfer viva questions and answers are essential for students and professionals preparing for engineering examinations, interviews, or practical assessments related to thermal sciences. Mastery over these questions not only helps in clearing viva voce sessions confidently but also deepens the understanding of fundamental heat transfer concepts that are vital in designing thermal systems. This comprehensive guide aims to cover the most frequently asked viva questions on heat transfer, along with detailed answers, to serve as a valuable resource for students preparing for their exams and interviews.

Introduction to Heat Transfer

Understanding the basics of heat transfer is fundamental before delving into specific viva questions. Heat transfer is the process of thermal energy movement from a hotter region to a cooler one, driven by temperature differences. The three main modes of heat transfer are conduction, convection, and radiation.

Common Heat Transfer Viva Questions and Their Answers

Below is a curated list of commonly asked viva questions along with detailed answers to help students prepare effectively.

1. Define heat transfer and its modes.

Heat transfer is the process of thermal energy transfer from one body or part of a body to another due to temperature difference. The three primary modes are:

- **Conduction:** Transfer of heat through a solid material without any movement of the material itself.
- **Convection:** Transfer of heat in fluids (liquids and gases) through bulk movement of molecules.
- **Radiation:** Transfer of heat through electromagnetic waves without the need for a medium.

2. What is Fourier's law of heat conduction?

Fourier's law states that the rate of heat conduction through a homogeneous, isotropic material is proportional to the negative gradient of temperature and the area normal to the heat flow. Mathematically:

$$\dot{Q} = -kA \frac{dT}{dx}$$

where:

- $\dot{Q}$ = heat transfer rate (W)
- k = thermal conductivity of the material (W/m·K)
- A = cross-sectional area (m²)
- dT/dx = temperature gradient (K/m)

3. Explain the concept of thermal conductivity.

Thermal conductivity (k) is a material property that measures the ability of a material to conduct heat. Materials with high thermal conductivity, like metals, transfer heat efficiently, whereas insulators like wood or rubber have low conductivity.

4. What is convective heat transfer? How is it quantified?

Convective heat transfer involves the transport of heat by the physical movement of fluid. It is characterized by the convective heat transfer coefficient (h), which relates the heat flux to the temperature difference between the surface and the fluid. The heat transfer rate is given by Newton's law of cooling:

$$Q = hA(T_s - T_\infty)$$

where:

- (T_s) = surface temperature
- (T_∞) = fluid temperature far from the surface

5. Describe the different types of convection.

Convection can be classified into:

- **Natural Convection:** Caused by buoyancy forces due to density differences resulting from temperature gradients.
- **Forced Convection:** Induced by external means such as fans or pumps.

6. What is radiation heat transfer? Explain the Stefan-Boltzmann law.

Radiation heat transfer is the transfer of energy through electromagnetic waves. The Stefan-Boltzmann law states that the power radiated per unit area of a blackbody is proportional to the fourth power of its absolute temperature:

$$E_b = \sigma T^4$$

where:

- (σ) = Stefan-Boltzmann constant (5.67×10^{-8} W/m²K⁴)
- (T) = absolute temperature in Kelvin

7. Define emissivity and its significance in heat transfer.

Emissivity (ϵ) is a measure of a material's ability to emit thermal radiation compared to a blackbody. It ranges from 0 to 1. A higher emissivity indicates better radiation emission. It influences the radiative heat transfer calculations:

$$Q = \epsilon \sigma A (T_s^4 - T_\infty^4)$$

8. Differentiate between steady-state and transient heat transfer.

In steady-state heat transfer, the temperature distribution does not change with time; the system reaches equilibrium. In transient heat transfer, temperatures vary with time, and the system is not in equilibrium.

9. Explain the concept of thermal resistance.

Thermal resistance quantifies the difficulty of heat flow through a material or interface. It is analogous to electrical resistance and is used to analyze composite heat transfer paths. For conduction:

$$R_{\text{cond}} = \frac{L}{kA}$$

where L is the thickness of the material.

10. What is the overall heat transfer coefficient?

The overall heat transfer coefficient (U) combines multiple resistances (conduction, convection, radiation) in a composite system. It is used to calculate heat transfer across multi-layered systems:

$$Q = U A \Delta T$$

where ΔT is the temperature difference between the outer surfaces.

Special Topics and Advanced Questions

To prepare thoroughly, students should also focus on advanced topics and typical viva questions related to real-world applications.

11. What are the assumptions made in lumped system analysis?

In lumped system analysis, the following assumptions are made:

- The Biot number (Bi) is less than 0.1, indicating negligible temperature gradient within the solid.
- The temperature of the object is uniform throughout at any instant.
- Heat transfer occurs mainly through conduction, with negligible internal resistance.

12. Derive the relation for transient conduction in a plane wall.

For a plane wall with initial uniform temperature T_i , cooled or heated at its surfaces, the temperature distribution over time can be derived using the heat conduction equation and separation of variables, leading to an infinite series solution involving eigenvalues. The temperature at the center of the wall at time t is given by:

$$T(t) = T_{\infty} + (T_i - T_{\infty}) \sum_{n=1}^{\infty} \frac{4}{\pi(2n-1)} \exp \left(- \frac{(2n-1)^2 \pi^2 \alpha t}{4L^2} \right)$$

where α is the thermal diffusivity.

13. How does the Biot number influence heat transfer analysis?

The Biot number (Bi) is a dimensionless parameter defined as:

$$Bi = \frac{hL_c}{k}$$

where:

- h = convective heat transfer coefficient
- L_c = characteristic length
- k = thermal conductivity
- If $Bi < 0.1$, temperature gradients within the object are negligible, and a lumped capacitance analysis is sufficient.
- If $Bi > 0.1$, temperature gradients within the object are significant, and more detailed analysis is required.

14. Explain the concept of heat exchanger effectiveness.

Heat exchanger effectiveness (ϵ) is a measure of how well a heat exchanger performs relative to its maximum possible heat transfer. It is defined as:

$$\epsilon = \frac{Q_{\text{actual}}}{Q_{\text{max}}}$$

where:

- Q_{actual} = actual heat transfer rate
- Q_{max} = maximum possible heat transfer rate, based on the inlet temperatures

15. List and explain the types of heat exchangers.

- **Parallel Flow Heat Exchanger:** Fluids flow in the same direction.
- **Counter Flow Heat Exchanger:** Fluids flow in opposite directions, offering higher efficiency.
- **Cross Flow Heat Exchanger:** Fluids cross each other at right angles.

Heat Transfer Viva Questions and Answers: An In-Depth Guide for Engineering Students

Heat transfer viva questions and answers form a crucial part of engineering examinations, especially for students specializing in mechanical, chemical, aerospace, and other related disciplines. Mastery over this subject not only helps secure good grades but also establishes a solid foundation for understanding thermal systems in practical applications. This comprehensive guide aims to clarify core concepts, typical questions, and effective answers, providing students with confidence for their viva voce exams.

Introduction to Heat Transfer

Heat transfer is the science of thermal energy exchange between physical systems due to temperature difference. It is fundamental to numerous engineering processes, from designing heat exchangers to understanding climate systems. The discipline primarily involves three modes: conduction, convection, and radiation, each governed by distinct principles but often interconnected in real-world scenarios.

Core Concepts of Heat Transfer

Before diving into specific viva questions, it's essential to grasp the basic concepts:

- Heat transfer modes: Conduction, convection, and radiation.
- Thermal conductivity: Material property indicating its ability to conduct heat.
- Heat flux: Rate of heat transfer per unit area.
- Steady vs. unsteady state: Whether the temperature distribution changes with time.
- Thermal resistance: Resistance to heat flow, analogous to electrical resistance.
- Heat exchangers: Devices designed to efficiently transfer heat between fluids.

Common Heat Transfer Viva Questions and Their Answers

Below, questions are categorized based on their complexity and focus areas, along with detailed explanations.

- Basic Conceptual Questions

Q1. What is heat transfer? Explain its importance in engineering.

Answer:

Heat transfer is the process of thermal energy movement from one point to another due to a temperature difference. It plays a vital role in numerous engineering applications such as heating and cooling systems, engines, refrigeration, and power plants. Understanding heat transfer helps engineers optimize energy consumption, improve system efficiency, and develop innovative thermal management solutions.

Q2. Describe the three modes of heat transfer.

Answer:

- Conduction: Transfer of heat within a solid or between solids in direct contact, driven by temperature gradients. Governed by Fourier's law, it is predominant in solids.
- Convection: Transfer of heat between a solid surface and a moving fluid (liquid or gas). It involves bulk fluid motion and can be natural or forced.
- Radiation: Transfer of heat through electromagnetic waves without needing a medium. All bodies emit and absorb thermal radiation, governed by Stefan-Boltzmann law.

- Quantitative and Analytical Questions

Q3. State Fourier's law of heat conduction and derive the expression for heat flux.

Answer:

Fourier's law states that the heat flux (q) through a homogeneous, isotropic solid is proportional to the negative of the temperature gradient:

$$q = -k \frac{dT}{dx}$$

where:

- (q) = heat flux (W/m^2)
- (k) = thermal conductivity of the material ($W/m \cdot K$)
- $(\frac{dT}{dx})$ = temperature gradient in the direction of heat transfer (K/m)

Derivation:

In steady state, assuming one-dimensional conduction, the rate of heat transfer (Q) through a slab of thickness (L) and area (A) :

$$Q = -kA \frac{\Delta T}{L}$$

Dividing both sides by A :

$$q = \frac{Q}{A} = -k \frac{\Delta T}{L}$$

This expression relates heat flux to the temperature difference across the material.

Q4. What is the Biot number? Explain its significance.

Answer:

The Biot number (Bi) is a dimensionless parameter defined as:

$$Bi = \frac{hL_c}{k}$$

where:

- h = convective heat transfer coefficient ($\text{W/m}^2\cdot\text{K}$)
- L_c = characteristic length (usually the ratio of volume to surface area) (m)
- k = thermal conductivity of the solid ($\text{W/m}\cdot\text{K}$)

Significance:

- If $Bi \ll 1$, internal conduction resistance is negligible compared to surface convection resistance, and the temperature within the body is nearly uniform.
- If $Bi \gg 1$, temperature gradients within the body are significant, and conduction resistance dominates.

- Mode-Specific Questions

Q5. How does Newton's law of cooling relate to convective heat transfer?

Answer:

Newton's law of cooling states that the rate of convective heat transfer from a surface to a fluid is proportional to the temperature difference between the surface and the fluid:

$$Q = hA(T_s - T_{\infty})$$

where:

- Q = heat transfer rate (W)
- h = convective heat transfer coefficient ($\text{W/m}^2\cdot\text{K}$)
- A = surface area (m^2)
- T_s = surface temperature (K)
- T_{∞} = fluid temperature far from the surface (K)

This law simplifies the analysis of convection, especially when dealing with steady-state problems.

Q6. Explain the concept of thermal radiation and Stefan-Boltzmann law.

Answer:

Thermal radiation is electromagnetic energy emitted by a body due to its temperature. All bodies emit and absorb thermal radiation, with intensity depending on temperature and surface properties. The Stefan-Boltzmann law quantifies the total radiative heat emitted per unit area:

$$E = \sigma T^4$$

where:

- E = emissive power (W/m^2)
- σ = Stefan-Boltzmann constant ($5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4$)
- T = absolute temperature (K)

For real surfaces, the law is modified by emissivity (ϵ):

$$E = \epsilon \sigma T^4$$

where ϵ ranges between 0 and 1.

- Practical and Application-Based Questions

Q7. Describe the working principle of a heat exchanger and name its types.

Answer:

A heat exchanger facilitates heat transfer between two or more fluids at different temperatures without mixing them. It operates on the principle of maximizing heat transfer surface area while minimizing flow resistance. Types include:

- Shell and Tube Heat Exchanger: Fluids flow through tubes enclosed within a shell.
- Double Pipe Heat Exchanger: Two concentric pipes with fluids flowing in counter or parallel directions.
- Plate Heat Exchanger: Multiple thin plates facilitate large surface area for heat transfer.
- Air Cooler and Condenser: Use air as the cooling or heating medium.

Q8. How do you calculate the overall heat transfer coefficient?

Answer:

The overall heat transfer coefficient (U) accounts for thermal resistances from conduction, convection, and radiation in a composite system:

$$\frac{1}{UA} = \frac{1}{h_i A} + \frac{L}{k A} + \frac{1}{h_o A}$$

or simplified as:

$$Q = U A \Delta T_{lm}$$

where:

- (Q) = heat transfer rate (W)
- (A) = heat transfer area (m^2)
- (ΔT_{lm}) = log mean temperature difference (K)

- Advanced and Conceptual Questions

Q9. What is the significance of the log mean temperature difference (LMTD) in heat exchanger analysis?

Answer:

LMTD is used to accurately compute the average temperature difference between the hot and cold fluids over the length of a heat exchanger, especially when the temperature difference varies along the flow path. It is given by:

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

where ΔT_1 and ΔT_2 are temperature differences at two ends.

LMTD simplifies the calculation of heat transfer rate in counter-flow and parallel-flow heat exchangers, ensuring precise design and analysis.

Q10. Explain the concept of critical radius of insulation.

Answer:

The critical radius of insulation is the minimum radius at which a cylindrical or spherical object's insulation prevents heat loss. If the insulation thickness is less than this radius, heat loss increases with increasing insulation thickness. It is derived from the balance between conduction and convection resistance:

For a cylinder:

$$r_{critical} = \frac{k}{h}$$

where:

- k = thermal conductivity of insulation
- h = convective heat transfer coefficient

Beyond this radius, adding more insulation reduces heat loss.

Conduction is predominant in solids but also occurs in stationary fluids. It relies on temperature gradients and the thermal conductivity of the material. The Fourier's Law describes this process:

$$Q = -k A (dT/dx)$$

where Q is heat transfer rate, k is thermal conductivity, A is cross-sectional area, and dT/dx is the temperature gradient.

Convection

Convection involves the movement of fluid, carrying thermal energy with it. It can be natural (due to buoyancy effects) or forced (using pumps or fans). The convective heat transfer coefficient (h) quantifies the efficiency of this process:

$$Q = h A (T_s - T_{\infty})$$

where T_s is the surface temperature, and T_{∞} is the bulk fluid temperature.

Radiation

Radiative heat transfer occurs through electromagnetic waves, especially significant at high

temperatures. The Stefan-Boltzmann Law governs this mode:

$$Q = \epsilon \sigma A T^4$$

where ϵ is emissivity, σ is the Stefan-Boltzmann constant, and T is absolute temperature.

Fluid Properties Relevant to Thermal Fluid Science

- **Density (ρ):** Mass per unit volume, influences buoyancy and flow behavior.
- **Viscosity (μ):** Measure of a fluid's resistance to deformation, affects flow regimes.
- **Specific Heat Capacity (c_p):** Amount of heat required to raise the temperature of a unit mass by one degree.

Reynolds Number: A Critical Dimensionless Parameter

Reynolds number (Re) helps determine flow regimes:

$$Re = (\rho v L) / \mu$$

where v is flow velocity, L is characteristic length, ρ is density, and μ is dynamic viscosity. Re influences system design choices, heat transfer rates, and pressure drops.
